Bounded Model Checking

- look only for counter example made of $k$ states
  \[ s_0 \rightarrow s_1 \rightarrow s_t \rightarrow s_{t+1} \rightarrow \ldots \rightarrow s_k \]
  \[ \neg p \rightarrow \neg p \rightarrow \neg p \rightarrow \neg p \rightarrow \neg p \]
  “$k$” = bound

- simple for safety properties $p$ invariantly true
  \[ I(s_0) \land T(s_0, s_1) \land \cdots \land T(s_{k-1}, s_k) \land \bigvee_{i=0}^{k} \neg p(s_i) \]

- harder for liveness properties $p$ eventually true
  \[ I(s_0) \land T(s_0, s_1) \land \cdots \land T(s_{k-1}, s_k) \land \bigwedge_{i=0}^{k} \neg p(s_i) \land \bigvee_{l=0}^{k} T(s_k, s_l) \]

- compute and bound $k$ by diameter

[BiereCimattiClarkeZhu’1999]
How did Bounded Model Checking happen?

- 1997: interest and capacity of BDDs stalled but there were success stories of “other” techniques. CAV’97 in Haifa had an invited talk by Arne Borålv on “The Industrial Success of Verification Tools Based on Stålmarck's Method”
- Edmund Clarke hired Yunshan Zhu and Armin Biere as Post-Docs with the job-description: *Use SAT for Symbolic Model Checking!* (YZ expert on Theorem Proving, AB on BDDs)
- struggled for 10 months to come up with something that could replace / improve on BDDs. mainly looked at QBF back then (point was that we need to handle quantifiers to do image computation)
- Alessandro Cimatti came to an AI conference in Pittsburg and at lunch (at an Indian Restaurant) we realized, that for planning they do not care about completeness. *What if we apply this to model checking? How to handle temporal logic?*
- after one afternoon for the theory and 3 months of implementation, benchmarking, writing it up …
Symbolic Model Checking without BDDs*

Abstract. Symbolic Model Checking [3, 14] has proven to be a powerful technique for the verification of reactive systems. BDDs [2] have traditionally been used as a symbolic representation of the system. In this paper we show how boolean decision procedures, like Stålmarck’s Method [16] or the Davis & Putnam Procedure [7], can replace BDDs. This new technique avoids the space blow up of BDDs, generates counterexamples much faster, and sometimes speeds up the verification. In addition, it produces counterexamples of minimal length. We introduce a bounded model checking procedure for LTL which reduces model checking to propositional satisfiability. We show that bounded LTL model checking can be done without a tableau construction. We have implemented a model checker \textbf{BMC}, based on bounded model checking, and preliminary results are presented.

Symbolic model checking using SAT procedures instead of BDDs

Authors: Armin Biere, Alessandro Cimatti, Edmund M Clarke, Masahiro Fujita, Yunshan Zhu

Publication date: 1999/6/1

Pages: 317-320

Publisher: ACM

Description: In this paper, we study the application of propositional decision procedures in hardware verification. In particular, we apply bounded model checking, as introduced in [1], to equivalence and invariant checking. We present several optimizations that reduce the size of generated propositional formulas. In many instances, our SAT-based approach can significantly outperform BDD-based approaches. We observe that SAT-based techniques are particularly efficient in detecting errors in both combinational and sequential designs.

Verifying Safety Properties of a PowerPC- Microprocessor Using Symbolic Model Checking without BDDs

Authors: Armin Biere, Edmund Clarke, Richard Raimi, Yunshan Zhu

Publication date: 1999/7/6

Conference: International Conference on Computer Aided Verification

Pages: 60-71

Publisher: Springer, Berlin, Heidelberg

Description: Abstract In [1] Bounded Model Checking with the aid of satisfiability solving (SAT) was introduced as an alternative to symbolic model checking with BDDs. In this paper we show how bounded model checking can take advantage of specialized optimizations. We present a bounded version of the cone of influence reduction. We have successfully applied this idea in checking safety properties of a PowerPC microprocessor at Motorola's Somerset PowerPC design center. Based on that experience, we propose a verification methodology that we feel can bring model checking into the mainstream of industrial chip design.

Bounded model checking.

Authors: Armin Biere, Alessandro Cimatti, Edmund M. Clarke, Ofer Strichman, Yunshan Zhu

Publication date: 2003/12

Journal: Advances in Computers

Volume: 58

Issue: 11

Pages: 117-148

Description: Symbolic model checking with Binary Decision Diagrams (BDDs) has been successfully used in the last decade for formally verifying finite state systems such as sequential circuits and protocols. Since its introduction in the beginning of the 90's, it has been integrated in the quality assurance process of several major hardware companies. The main bottleneck of this method is that BDDs may grow exponentially, and hence the amount of available memory restricts the size of circuits that can be verified efficiently. In this article we survey a technique called Bounded Model Checking (BMC), which uses a propositional SAT solver rather than BDD manipulation techniques. Since its introduction in 1999, BMC has been well received by the industry. It can find many logical errors in complex systems that can not be handled by competing techniques, and is therefore widely perceived as a complementary ...
Bounded model checking using satisfiability solving

Authors: Edmund Clarke, Armin Biere, Richard Raimi, Yunshan Zhu
Publication date: 2001/7/1
Journal: Formal methods in system design
Volume: 19
Issue: 1
Pages: 7-34
Publisher: Kluwer Academic Publishers
Description: The phrase model checking refers to algorithms for exploring the state space of a transition system to determine if it obeys a specification of its intended behavior. These algorithms can perform exhaustive verification in a highly automatic manner, and, thus, have attracted much interest in industry. Model checking programs are now being commercially marketed.
However, model checking has been held back by the state explosion problem, which is the problem that the number of states in a system grows exponentially in the number of system components. Much research has been devoted to ameliorating this problem. In this tutorial, we first give a brief overview of the history of model checking to date, and then focus on recent techniques that combine model checking with satisfiability solving. These techniques, known as bounded model checking, do a very fast exploration of the state space, and for...

Abstract. Formal verification of arithmetic datapaths has been part of the established methodology for most Intel processor designs over the last years, usually in the role of supplementing more traditional coverage oriented testing activities. For the recent Intel® Core™ i7 design we took a step further and used formal verification as the primary validation vehicle for the core execution cluster, the component responsible for the functional behaviour of all microinstructions. We applied symbolic simulation based formal verification techniques for full datapath, control and state validation for the cluster, and dropped coverage driven testing entirely. The project, involving some twenty person years of verification work, is one of the most ambitious formal verification efforts in the hardware industry to date. Our experiences show that under the right circumstances, full formal verification of a design component is a feasible, industrially viable and competitive validation approach.

6 Formal Verification Value Proposition

The conventional wisdom about formal verification in industrial contexts is easy to spell out: doing formal verification is too expensive. However, thorough effort only a few years back could lead to a perceived low return on investment. The areas where projects have routinely chosen to do formal verification have then been limited to those where an uncaught problem would be so visible and costly that the extra effort of doing formal verification can be justified. As a positive exception, SAT-based bounded model checking has been very successfully used as a bug-hunting tool in targeted areas.

The third usage model, mixing formal and dynamic techniques on validating a single design, includes interesting aspects of full design and verification integration.
Impact

- widespread use in industry (EDA)
  - industry embraced bounding part immediately
  - original *industrial* reservations: using SAT vs ATPG
  - original *academic* reservations: incompleteness?
- BMC relies on efficient SAT (SMT) solving
  - breakthroughs in SAT: CDCL '96, VSIDS '01, ...
  - encouraged investment in SAT / SMT research
- extensions to *completeness*
  - diameter checking, $k$-induction, interpolation
  - SAT based model checking *without* unrolling: IC3
- extensions to *non-boolean* domains
  - infinite state systems
  - bounding reduces complexity & increases decidability
  - software

A Tool for Checking ANSI-C Programs

Edmund Clarke, Daniel Kroening, and Flavio Lerda
Carnegie Mellon University

Abstract. We present a tool for the formal verification of ANSI-C programs using Bounded Model Checking (BMC). The emphasis is on usability: the tool supports almost all ANSI-C language features, including pointer constructs, dynamic memory allocation, recursion, and the float and double data types. From the perspective of the user, the verification is highly automated: the only input required is the BMC bound. The tool is integrated into a graphical user interface. This is essential for presenting long counterexample traces: the tool allows stepping through the trace in the same way a debugger allows stepping through a program.

1 Introduction

We present a tool that uses Bounded Model Checking to reason about low-level ANSI-C programs. There are two applications of the tool: 1) the tool checks safety properties such as the correctness of pointer constructs, and 2) the tool can compare an ANSI-C program with another design, such as a circuit given in Verilog.
A tool for checking ANSI-C programs

SATABS: SAT-based predicate abstraction for ANSI-C

Authors: Edmund Clarke, Daniel Kroening, Natasha Sharygina, Karen Yorav

Publication date: 2005/4/4

Conference: International Conference on Tools and Algorithms for the Construction and Analysis of Systems

Pages: 570-574

Publisher: Springer, Berlin, Heidelberg

Description: This paper presents a model checking tool, SatAbs, that implements a predicate abstraction refinement loop. Existing software verification tools such as Slam, Blast, or Magic use decision procedures for abstraction and simulation that are limited to integers. SatAbs overcomes these limitations by using a SAT-solver. This allows the model checker to handle the semantics of the ANSI-C standard accurately. This includes a sound treatment of bit-vector overflow, and of the ANSI-C pointer arithmetic constructs.

Behavioral consistency of C and Verilog programs using bounded model checking

Authors: Edmund Clarke, Daniel Kroening, Karen Yorav
Publication date: 2003/6/2
Pages: 368-371
Publisher: IEEE

Description: We present an algorithm that checks behavioral consistency between an ANSI-C program and a circuit given in Verilog using Bounded Model Checking. Both the circuit and the program are unwound and translated into a formula that represents behavioral consistency. The formula is then checked using a SAT solver. We are able to translate C programs that include side effects, pointers, dynamic memory allocation, and loops with conditions that cannot be evaluated statically. We describe experimental results on various reactive circuits and programs, including a small processor given in Verilog and its Instruction Set Architecture given in ANSI-C.

Applied Impact of CBMC

- 2011: HVC Award, recognizing the most promising academic and industrial contribution to the fields of testing and software and hardware verification from the preceding five years.
- 2014: CBMC overall winner of the Software Verification Competition (TACAS SV-COMP)
- Since 2014: BTC ships CBMC as part of their Embedded Tester product
- 2016: Diffblue Ltd spin-out founded
- 2017: CBMC best bug-finder in TACAS SV-COMP
- 2018: five of the six contestants in SV-COMP’s Concurrency category use CBMC or are forks of CBMC, eight of 21 tools participating in SV-COMP use CBMC or are forks
- Industrial users include Amazon, ARM, TATA, Toyota
Lessons

- simple but very useful ideas are highly controversial
  - hard to get accepted (literally)
  - also got many comments of the sort: *we did this before* ...
  - main points: don’t be afraid, make it work, show that it works!
- in retrospective
  - complexity classification considerations (so more theory)
    might have been useful since we tried to use SAT for symbolic model checking without taking Savitch's theorem into account
  - but might also have prevented us going along that route ...
