Improving stochastic local search for  
SAT with a new probability distribution

## Introduction

### SAT

- ▶ Formula  $F$  as a set of clauses. Each clause as a set of literals.
- ▶ Is there an assignment  $\alpha$ , so that  $F(\alpha) = 1$ ?

### SLS-solvers

- ▶ Operate on complete assignments.
- ▶ Try to change an initial assignment  $\alpha_0$  in a way, so that it becomes satisfying after several steps.
- ▶ Use local information and heuristics to decide how to modify the assignment in each search step.

## Pseudocode of a typical SLS-solver

INPUT: formula  $F$ , cutoff.

OUTPUT: model for  $F$  or UNKNOWN.

SLS( $F$ , cutoff)

**for**  $i=1$  to maxTries

$\alpha = \alpha_0 =$  random assignment;

**for**  $j=1$  to maxFlips

**if** ( $\alpha$  is a model for  $F$ ) **return**  $\alpha$ ;

var = pickVar ();

$\alpha[\text{var}] = 1 - \alpha[\text{var}]$ ;

**return** UNKNOWN;

## SLS architectures

- ▶ Differ in how to select a variable for flipping.

### GSAT

- ▶ Considers all variables.

### WalkSAT

- ▶ Only considers variables from a randomly chosen unsatisfied clause.

### DLS

- ▶ Similar to GSAT. Additionally uses clause-weighting.

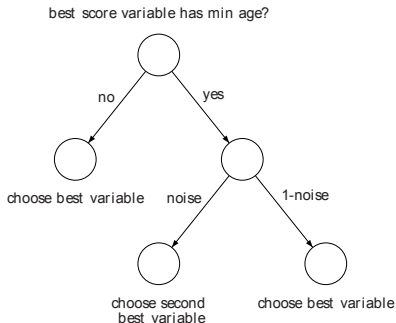

## Modern SLS-solvers

- ▶ Can not be put into just one category.
- ▶ Are hybrids of the different architectures e.g.:
  - ▶ adaptG2WSAT = GSAT + WalkSAT + adaptive scheme [Li07]
  - ▶ gNovelty+ = adaptG2WSAT + DLS-component [Pham07]
  - ▶ TNM = GSAT + WalkSAT-version + two noise schemes to switch between [Wei09]
- ▶ they all use a Novelty-version to escape from local minima.

## Escaping from local minima

### Novelty

- ▶ Choose a random unsatisfied clause  $c \in F$
- ▶ Pick a variable  $x$  from  $c$  according to the following heuristic:

## Escaping from local minima

### adaptNovelty+

- ▶ Additionally implements a random walk with probability  $wp$ .
- ▶ Uses an adaptive scheme for setting the noise probability [Hoos02].

## Novelty as a probability distribution

- ▶ This can be seen as a probability distribution  $p$  on the variables of  $c$ .
- ▶  $p(x)$  can take only 4 different values:
  - ▶ Always chosen;  $p(x) = 1$
  - ▶ Chosen, when no noise step occurs;  $p(x) = (1 - noise)$
  - ▶ Chosen, when a noise step occurs;  $p(x) = noise$
  - ▶ Never chosen;  $p(x) = 0$
- ▶ Information used to decide: *score*, *age*
- ▶ Does not take into account the exact values of *score* and *age*.
- ▶ Does not put different variables into relation.

## Example

- ▶  $C = \{x_1, x_2, x_3\}$

### Case 1

- ▶  $score(x_1) = 0, score(x_2) = -3, score(x_3) = -3$
- ▶  $age(x_1) = 10^4 - 2, age(x_2) = 10^4, age(x_3) = 10^4 - 1$

### Case 2

- ▶  $score(x_1) = -1, score(x_2) = -2, score(x_3) = -3$
  - ▶  $age(x_1) = 10^3, age(x_2) = 10^4, age(x_3) = 10^7$
- ▶ Both cases are identical for Novelty+.
  - ▶ The only chance for  $x_3$  to be selected is by a random walk.

## New probability distribution

- ▶ Define a probability distribution as a concatenation of continuous functions on the variables of  $c$ .
- ▶ Choose a random variable according to this distribution.
- ▶ The form of this distribution  $p(x) := \frac{p_s(x) \cdot p_a(x)}{\sum_{\tilde{x} \in c} p_s(\tilde{x}) \cdot p_a(\tilde{x})}$ .
- ▶  $p_s(x)$  is a function considering the *score* of  $x$ .
- ▶  $p_a(x)$  is a function considering the *age* of  $x$ .
- ▶  $p_a(x), p_s(x) > 0$

## New probability distribution

- ▶ Define a probability distribution as a concatenation of continuous functions on the variables of  $c$ .
- ▶ Choose a random variable according to this distribution.
- ▶ The form of this distribution  $p(x) := \frac{p_s(x) \cdot p_a(x)}{\sum_{\tilde{x} \in c} p_s(\tilde{x}) \cdot p_a(\tilde{x})}$ .
- ▶  $p_s(x) := c_1^{\text{score}(x)}$
- ▶  $p_a(x) := \left( \frac{\text{age}(x)}{c_3} \right)^{c_2} + 1$
- ▶  $c_1$  controls the influence of *score* on the decision.
- ▶  $c_2$  and  $c_3$  specify, how quick and how strong *age* starts to affect the decision.

## Properties of $p$

### Like Novelty

- ▶ Prefers variables with high *score*.
- ▶ Prefers variables with high *age*.

### Additionally

- ▶ Takes into account the exact values of *score* and *age*.
- ▶ Puts different variables into relation.
- ▶ Does not need an explicit random walk.
  - ▶ Implicit random walk because of  $p_s(x), p_a(x) > 0$ .
- ▶ Does not need an explicit noise scheme.
  - ▶ Growing age automatically leads to new decisions when getting stuck in a certain part of the search space.

## Implementation details

### *Sparrow*

- ▶ gNovelty+ as the basic module. gNovelty+ consists of:
  - ▶ Gradient-walk as in G2WSAT.
  - ▶ adaptNovelty+ to escape local minima.
  - ▶ Additive weighting scheme.
- ▶ Replaced the adaptNovelty+ component by a WalkSAT-algorithm using the presented probability distribution.
- ▶ Specifying the parameters  $c_1 = 4, c_2 = 4, c_3 = 10^5$ .
  - ▶ Constants fixed for all instances.
  - ▶ Empirical values.
  - ▶ Not optimized yet.

## Evaluation

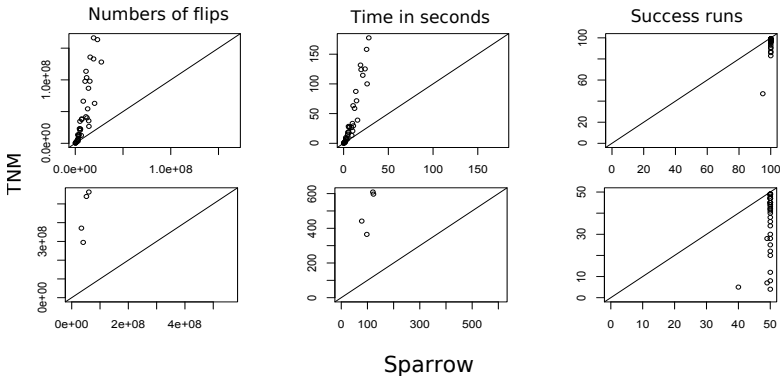

### Empirical Tests

- ▶ 2 sets of large random 3-SAT instances with  $ratio = 4.2$
- ▶ Not optimized for  $k$ -SAT,  $k \neq 3$ .
- ▶ Benchmark 1:
  - ▶ 64 different instances from SAT 2009 Competition (2k - 18k variables)
  - ▶ Each instance is solved 100 times (cutoff 1200 sec.)
- ▶ Benchmark 2:
  - ▶ 40 additional instances from SAT 2009 Competition (20k - 26k variables)
  - ▶ Each instance is solved 50 times (cutoff 2400 sec.)

## Results: Sparrow vs gNovelty+

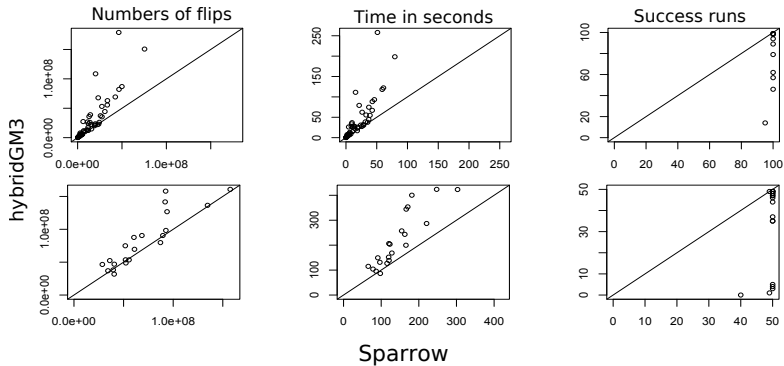

## Results: Sparrow vs TNM

## Results: Sparrow vs hybridGM3

## Conclusion

### Summary

- ▶ Escaping local minima is a key feature for SLS-solvers
- ▶ Variable selection in local minima should not be done in a deterministic way
- ▶ Detailed differentiation useful for variable selection.

### Outlook

- ▶ Implement more attributes.
- ▶ Arbitrary complex function.
- ▶ Variable expressions [Tompkins10].
