Decision Procedures and SMT

#342.255

http://fmv.jku.at/kv

WS 2016/2017

Johannes Kepler University

Linz, Austria

Prof. Dr. Armin Biere

Institute for Formal Models and Verification

http://fmv.jku.at
Overview

Part I  Lecture on October 24
- 11:00 - 12:00 Introduction and Encoding into SAT
- 13:00 - 14:00 Basic Algorithms and Data Structures
- 14:30 - 15:30 Learning and Advanced Data Structures
- 16:00 - 17:30 Preprocessing and Inprocessing
- 17:30 - 18:00 Assignment and Closing

Part II  Presentations
- each participant has to present two papers on a related subject
- 2 days of presentation closer to the end of the semester
What is Practical SAT Solving?

- Encoding
- Simplifying
- Reencoding
- Inprocessing
- Search
- CDCL
SAT Example: Equivalence Checking if-then-else Chains

original C code

```c
if(!a && !b) h();
else if(!a) g();
else f();
```

⇑

```c
if(!a)
  {
    if(a) f();
    if(!b) h();
  } else
  {
    else g();
    if(!b) h();
  }
else f();
```

⇑

optimized C code

```c
if(a) f();
else if(b) g();
else h();
```

How to check that these two versions are equivalent?
1. represent procedures as *independent* boolean variables

\[
\begin{align*}
\text{original} & : = \\
\text{optimized} & : = \\
\text{if } \neg a \land \neg b & \text{ then } h \\
\text{else if } \neg a & \text{ then } g \\
\text{else } f & \\
\text{if } a & \text{ then } f \\
\text{else if } b & \text{ then } g \\
\text{else } h & \\
\end{align*}
\]

2. compile if-then-else chains into boolean formulae

\[
\text{compile}(\text{if } x \text{ then } y \text{ else } z) \equiv (x \land y) \lor (\neg x \land z)
\]

3. check equivalence of boolean formulae

\[
\text{compile(}\text{original}\text{)} \iff \text{compile(}\text{optimized}\text{)}
\]
original \equiv \text{if } \neg a \land \neg b \text{ then } h \text{ else if } \neg a \text{ then } g \text{ else } f \\
\equiv (\neg a \land \neg b) \land h \lor \neg (\neg a \land \neg b) \land \text{if } \neg a \text{ then } g \text{ else } f \\
\equiv (\neg a \land \neg b) \land h \lor \neg (\neg a \land \neg b) \land (\neg a \land g \lor a \land f)

optimized \equiv \text{if } a \text{ then } f \text{ else if } b \text{ then } g \text{ else } h \\
\equiv a \land f \lor \neg a \land \text{if } b \text{ then } g \text{ else } h \\
\equiv a \land f \lor \neg a \land (b \land g \lor \neg b \land h)

(\neg a \land \neg b) \land h \lor \neg (\neg a \land \neg b) \land (\neg a \land g \lor a \land f) \iff a \land f \lor \neg a \land (b \land g \lor \neg b \land h)
How to Check (In)Equivalence?

Reformulate it as a satisfiability (SAT) problem:

Is there an assignment to $a, b, f, g, h,$ which results in different evaluations of original and optimized?

or equivalently:

Is the boolean formula $\text{compile}(\text{original}) \not\leftrightarrow \text{compile}(\text{optimized})$ satisfiable?

such an assignment would provide an easy to understand counterexample

**Note:** by concentrating on counterexamples we moved from Co-NP to NP (this is just a theoretical note and not really important for applications)
SAT Example: Circuit Equivalence Checking

\[ b \lor a \land c \quad \Leftrightarrow \quad (a \lor b) \land (b \lor c) \]
**SAT (Satisfiability)** the classical NP complete Problem:

Given a propositional formula $f$ over $n$ propositional variables $V = \{x, y, \ldots\}$.

Is there an assignment $\sigma : V \rightarrow \{0, 1\}$ with $\sigma(f) = 1$?

**SAT belongs to NP**

There is a *non-deterministic* Touring-machine deciding SAT in polynomial time:

*guess* the assignment $\sigma$ (linear in $n$), calculate $\sigma(f)$ (linear in $|f|$)

**Note:** on a *real* (deterministic) computer this would still require $2^n$ time

**SAT is complete for NP** (see complexity / theory class)

**Implications for us:**

general SAT algorithms are probably exponential in time (unless NP = P)
**Definition**

A formula in **Conjunctive Normal Form (CNF)** is a conjunction of clauses

\[ C_1 \land C_2 \land \ldots \land C_n \]

Each clause \( C \) is a disjunction of literals

\[ C = L_1 \lor \ldots \lor L_m \]

And each literal is either a plain variable \( x \) or a negated variable \( \overline{x} \).

**Example**

\[ (a \lor b \lor c) \land (\overline{a} \lor \overline{b}) \land (\overline{a} \lor \overline{c}) \]

**Note 1:** two notions for negation: in \( \overline{x} \) and \( \neg \) as in \( \neg x \) for denoting negation.

**Note 2:** the original SAT problem is actually formulated for CNF

**Note 3:** SAT solvers mostly also expect CNF as input
**Assumption:** we only have conjunction, disjunction and negation as operators.

a formula is in Negation Normal Form (NNF),
if negations only occur in front of variables

⇒ all *internal* nodes in the formula tree are either ANDs or ORs

linear algorithms for generating NNF from an arbitrary formula

often NNF generations includes elimination of other non-monotonic operators:

\[
\text{NNF of } f \leftrightarrow g \text{ is NNF of } f \land g \lor \overline{f} \land \overline{g}
\]

in this case the result can be exponentially larger (see parity example later).
NNF Algorithm

Formula

formula2nnf (Formula f, Boole sign)
{
    if (is_variable (f))
        return sign ? new_not_node (f) : f;
    if (op (f) == AND || op (f) == OR)
    {
        l = formula2nnf (left_child (f), sign);
        r = formula2nnf (right_child (f), sign);
        flipped_op = (op (f) == AND) ? OR : AND;
        return new_node (sign ? flipped_op : op (f), l, r);
    }
    else
    {
        assert (op (f) == NOT);
        return formula2nnf (child (f), !sign);
    }
}
Simple Translation of Formula into CNF

Formula
formula2cnf_aux (Formula f)
{
  if (is_cnf (f))
    return f;
  if (op (f) == AND)
    {
      l = formula2cnf_aux (left_child (f));
      r = formula2cnf_aux (right_child (f));
      return new_node (AND, l, r);
    }
  else
    {
      assert (op (f) == OR);
      l = formula2cnf_aux (left_child (f));
      r = formula2cnf_aux (right_child (f));
      return merge_cnf (l, r);
    }
}
Merging two CNFs

Formula
formula2cnf (Formula f)
{
    \textbf{return} formula2cnf\_aux (formula2nnf (f, 0));
}

Formula
merge\_cnf (Formula f, Formula g)
{
    res = new\_constant\_node (TRUE);
    for (c = first\_clause (f); c; c = next\_clause (f, c))
        for (d = first\_clause (g); d; d = next\_clause (g, d))
            res = new\_node (AND, res, new\_node (OR, c, d));
    \textbf{return} res;
}
DAG may be exponentially more succinct than expanded Tree

**Examples:** adder circuit, parity, mutual exclusion
Boole
parity (Boole a, Boole b, Boole c, Boole d, Boole e,
        Boole f, Boole g, Boole h, Boole i, Boole j)
{
    tmp0 = b ? !a : a;
    tmp1 = c ? !tmp0 : tmp0;
    tmp2 = d ? !tmp1 : tmp1;
    tmp3 = e ? !tmp2 : tmp2;
    tmp4 = f ? !tmp3 : tmp3;
    tmp5 = g ? !tmp4 : tmp4;
    tmp6 = h ? !tmp5 : tmp5;
    tmp7 = i ? !tmp6 : tmp6;
    \textbf{return} j ? !tmp7 : tmp7;
}

Eliminiate the tmp... variables through substitution.

What is the size of the DAG vs the Tree representation?
How to detect Sharing

- through caching of results in algorithms operating on formulas (examples: substitution algorithm, generation of NNF for non-monotonic ops)
- when modeling a system: variables are introduced for subformulæ (then these variables are used multiple times in the toplevel formula)
- structural hashing: detects structural identical subformulæ (see Signed And Graphs later)
- equivalence extraction: e.g. BDD sweeping, Stålmárcks Method (we will look at both techniques in more detail later)
Example of Tseitin Transformation: Circuit to CNF

CNF

\[ o \land (x \rightarrow a) \land (x \rightarrow c) \land (x \leftarrow a \land c) \land \ldots \]

\[ o \land (\bar{x} \lor a) \land (\bar{x} \lor c) \land (x \lor \bar{a} \lor \bar{c}) \land \ldots \]
1. for each non input circuit signal $s$ generate a new variable $x_s$

2. for each gate produce complete input / output constraints as clauses

3. collect all constraints in a big conjunction

the transformation is *satisfiability equivalent*: the result is satisfiable iff the original formula is satisfiable

not equivalent in the classical sense to original formula: it has new variables

extract satisfying assignment for original formula, from one of the result (just project satisfying assignment onto the original variables)
Tseitin Transformation: Input / Output Constraints

Negation: \( x \leftrightarrow \bar{y} \) \( \iff \) \((x \rightarrow \bar{y}) \land (\bar{y} \rightarrow x)\)
\( \iff \) \((\bar{x} \lor \bar{y}) \land (y \lor x)\)

Disjunction: \( x \leftrightarrow (y \lor z) \) \( \iff \) \((y \rightarrow x) \land (z \rightarrow x) \land (x \rightarrow (y \lor z))\)
\( \iff \) \((\bar{y} \lor x) \land (\bar{z} \lor x) \land (\bar{x} \lor y \lor z)\)

Conjunction: \( x \leftrightarrow (y \land z) \) \( \iff \) \((x \rightarrow y) \land (x \rightarrow z) \land ((y \land z) \rightarrow x)\)
\( \iff \) \((\bar{x} \lor y) \land (\bar{x} \lor z) \land ((\bar{y} \land z) \lor y)\)
\( \iff \) \((\bar{x} \lor y) \land (\bar{x} \lor z) \land (\bar{y} \lor z \lor y)\)

Equivalence: \( x \leftrightarrow (y \leftrightarrow z) \) \( \iff \) \((x \rightarrow (y \leftrightarrow z)) \land ((y \leftrightarrow z) \rightarrow x)\)
\( \iff \) \((x \rightarrow ((y \rightarrow z) \land (z \rightarrow y)) \land ((y \leftrightarrow z) \rightarrow x)\)
\( \iff \) \((x \rightarrow (y \rightarrow z)) \land (x \rightarrow (z \rightarrow y)) \land ((y \leftrightarrow z) \rightarrow x)\)
\( \iff \) \((\bar{x} \lor \bar{y} \lor z) \land (\bar{x} \lor z \lor y) \land ((y \leftrightarrow z) \rightarrow x)\)
\( \iff \) \((\bar{x} \lor \bar{y} \lor z) \land (\bar{x} \lor z \lor y) \land (y \lor z) \land ((\bar{y} \land \bar{z}) \rightarrow x)\)
\( \iff \) \((\bar{x} \lor \bar{y} \lor z) \land (\bar{x} \lor z \lor y) \land (\bar{y} \lor z \lor x) \land (y \lor z \lor x)\)
Optimizations for Tseitin Transformation

- goal is smaller CNF (less variables, less clauses)
- extract multi argument operands (removes variables for intermediate nodes)
- half of AND, OR node constraints can be removed for *unnegated* nodes

A node occurs negated if it has an ancestor which is a negation

Half of the constraints determine parent assignment from child assignment

Those are unnecessary if node is not used negated

[PlaistedGreenbaum’86] and then [ChambersManoliosVroon’09]

- structural circuit optimizations like in the ABC tool from Berkeley
- however might be simulated on CNF level [JärvisaloBiereHeule-TACAS’10]
- compact technology mapping based encoding [EénMishchenkoSörensson’07]
Encoding directly into CNF is hard, so we use intermediate levels:

1. application level

2. bit-precise semantics world-level operations: bit-vector theory

3. bit-level representations such as AIGs or vectors of AIGs

4. CNF

- encoding application level formulas into word-level: as generating machine code
- word-level to bit-level: bit-blasting similar to hardware synthesis
- encoding “logical” constraints is another story
addition of 4-bit numbers $x, y$ with result $s$ also 4-bit: \[ s = x + y \]

\[
[s_3, s_2, s_1, s_0]_{4} = [x_3, x_2, x_1, x_0]_{4} + [y_3, y_2, y_1, y_0]_{4}
\]

\[
[s_3, \cdot]_{2} = \text{FullAdder}(x_3, y_3, c_2)
\]
\[
[s_2, c_2]_{2} = \text{FullAdder}(x_2, y_2, c_1)
\]
\[
[s_1, c_1]_{2} = \text{FullAdder}(x_1, y_1, c_0)
\]
\[
[s_0, c_0]_{2} = \text{FullAdder}(x_0, y_0, false)
\]

where

\[
[s, o]_{2} = \text{FullAdder}(x, y, i)
\]

with

\[
s = x \text{ xor } y \text{ xor } i
\]
\[
o = (x \land y) \lor (x \land i) \lor (y \land i) = ((x + y + i) \geq 2)
\]
And-Inverter-Graphs (AIG)

- widely adopted bit-level intermediate representation
  - see for instance our AIGER format [http://fmv.jku.at/aiger](http://fmv.jku.at/aiger)
  - used in Hardware Model Checking Competition (HWMCC)
  - also used in the *structural track* in SAT competitions
  - many companies use similar techniques

- basic logical operators: *conjunction* and *negation*

- DAGs: nodes are conjunctions, negation/sign as *edge attribute*

  bit stuffing: signs are compactly stored as LSB in pointer

- automatic sharing of isomorphic graphs, constant time (peep hole) simplifications

- *or even* SAT sweeping, full reduction, etc . . . see ABC system from Berkeley
XOR as AIG

\[ x \text{ xor } y \equiv (\overline{x} \land y) \lor (x \land \overline{y}) \equiv \overline{(\overline{x} \land y)} \land \overline{(x \land \overline{y})} \]

negation/sign are edge attributes
not part of node
typedef struct AIG { 
enum Tag tag;                 /* AND, VAR */
void *data[2];
int mark, level;              /* traversal */
AIG *next;                    /* hash collision chain */
};

#define sign_aig(aig) (1 & (unsigned) aig)
#define not_aig(aig) ((AIG*)(1 ^ (unsigned) aig))
#define strip_aig(aig) ((AIG*)(~1 & (unsigned) aig))
#define false_aig ((AIG*) 0)
#define true_aig ((AIG*) 1)

assumption for correctness:
sizeof(unsigned) == sizeof(void*)
4-bit adder

8-bit adder
bit-vector of length 16 shifted by bit-vector of length 4
Tseitin’s construction suitable for most kinds of “model constraints”
  - assuming simple operational semantics: encode an interpreter
  - small domains: one-hot encoding
  - large domains: binary encoding

harder to encode properties or additional constraints
  - temporal logic / fix-points
  - environment constraints

example for fix-points / recursive equations:
  \[ x = (a \lor y), \quad y = (b \lor x) \]
  - has unique least fix-point \[ x = y = (a \lor b) \]
  - and unique largest fix-point \[ x = y = \text{true} \]
  - only largest fix-point can be (directly) encoded in SAT
    otherwise need ASP
Example of Logical Constraints: Cardinality Constraints

- Given a set of literals \( \{l_1, \ldots, l_n\} \)
  - Constraint the *number* of literals assigned to *true*
    \[ |\{l_1, \ldots, l_n\}| \geq k \quad \text{or} \quad |\{l_1, \ldots, l_n\}| \leq k \quad \text{or} \quad |\{l_1, \ldots, l_n\}| = k \]

- Multiple encodings of cardinality constraints
  - Naïve encoding exponential: *at-most-two* quadratic, *at-most-three* cubic, etc.
  - Quadratic \( O(k \cdot n) \) encoding goes back to Shannon
  - Linear \( O(n) \) parallel counter encoding [Sinz’05]
  - For an \( O(n \cdot \log n) \) encoding see Prestwich’s chapter in our Handbook of SAT

- Generalization *Pseudo-Boolean* constraints (PB), e.g.
  \[ 2 \cdot \overline{a} + \overline{b} + c + \overline{d} + 2 \cdot e \geq 3 \]
  Actually used to handle MaxSAT in SAT4J for configuration in Eclipse
BDD based Encoding of Cardinality Constraints

\[ 2 \leq |\{l_1, \ldots, l_9\}| \leq 3 \]

```
\begin{array}{ccccccc}
l_1 & \cdots & l_2 & \cdots & l_3 & \cdots & l_4 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
l_2 & \cdots & l_3 & \cdots & l_4 & \cdots & l_5 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
l_3 & \cdots & l_4 & \cdots & l_5 & \cdots & l_6 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
l_4 & \cdots & l_5 & \cdots & l_6 & \cdots & l_7 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & 0 & 0 & 0 & 0 & 0 & 0
\end{array}
```

“then” edge downward, “else” edge to the right
Davis & Putnam Procedure (DP)

- dates back to the 50’ies:
  - original version is *resolution based* (successful only in preprocessors)
  - improved DPLL: case analysis (try $x = 0, 1$ in turn and recurse)
  - evolved to CDCL (conflict driven clause learning): state-of-the-art

- recent ($\leq 20$ years) optimizations:
  - backjumping, learning, UIPs, dynamic splitting heuristics, fast data structures
    we will have a look at each of them

- elimination procedure of original DP is similar to
  - Gaussian elimination on linear real equalities
  - Fourier-Motzikin on linear real inequalities
  - Buchberger’s algorithm on polynomial equations
- basis for first (less successful) resolution based DP
- can be extended to first order logic
- helps to explain learning

**Resolution Rule**

\[
C \cup \{v\} \quad D \cup \{\neg v\}
\]

\[
\frac{\{v, \neg v\} \cap C = \{v, \neg v\} \cap D = \emptyset}{C \cup D}
\]

**Read:** resolving the clause \(C \cup \{v\}\) with the clause \(D \cup \{\neg v\}\), both above the line, on the variable \(v\), results in the clause \(D \cup C\) below the line.
Usage of such rules: if you can derive what is above the line (premise) then you are allowed to deduce what is below the line (conclusion).

**Theorem.** (premise satisfiable $\Rightarrow$ conclusion satisfiable)

$$\sigma(C \cup \{v\}) = \sigma(D \cup \{\neg v\}) = 1 \quad \Rightarrow \quad \sigma(C \cup D) = 1$$

**Proof.**

let $c \in C$, $d \in D$ with $(\sigma(c) = 1$ or $\sigma(v) = 1$) and $(\sigma(d) = 1$ or $\sigma(\neg v) = 1$)

if $\sigma(c) = 1$ or $\sigma(d) = 1$ conclusion follows immediately

otherwise $\sigma(v) = \sigma(\neg v) = 1 \quad \Rightarrow$ contradiction

q.e.d.
**Theorem.** (conclusion satisfiable ⇒ premise satisfiable)

\[ \sigma(C \cup D) = 1 \implies \exists \sigma' \text{ with } \sigma'(C \cup \{v\}) = \sigma'(D \cup \{\neg v\}) = 1 \]

**Proof.**

with out loss of generality pick \( c \in C \) with \( \sigma(c) = 1 \)

define \( \sigma'(x) = \begin{cases} 0 & \text{if } x = v \\ \sigma(x) & \text{else} \end{cases} \)

since \( v \) and \( \neg v \) do not occur in \( C \), we still have \( \sigma'(C) = 1 \) and thus \( \sigma'(C \cup \{v\}) = 1 \)

by definition \( \sigma'(-v) = 1 \) and thus \( \sigma'(D \cup \{\neg v\}) = 1 \)

q.e.d.

**Example** consider incorrect resolution \( \frac{\{v\} \cup \{v\}}{\neg v} \) violating side condition
consider the following resolution
\[ \begin{array}{c}
a \lor b \\
\neg b \lor c \\
a \lor c
\end{array} \]

in logical notation, not set notation for a change

let \( \sigma(x) = \begin{cases} 
1 & \text{if } x = a \\
1 & \text{if } x = b \\
0 & \text{if } x = c
\end{cases} \)

be a model of resolvent \((a \lor c)\) thus \(\sigma(a \lor c) = 1\)

note that \(\sigma(\neg b \lor c) = 0\) and thus \(\sigma\) is not a model of 2nd antecedent (2nd premisse)

however \(\sigma\) satisfies remaining literal \(a\) of 1st antecedent in resolvent

thus simply flip value of pivot \(b\) (satisfy its occurrence in 2nd antecedent)

we get \(\sigma'(x) = \begin{cases} 
1 & \text{if } x = a \\
0 & \text{if } x = b \\
0 & \text{if } x = c
\end{cases} \)
satisfying both antecedents \(\sigma'(a \lor b) = \sigma'(\neg b \lor c) = 1\).
Idea: use resolution to existentially quantify out variables

1. if empty clause found then terminate with result unsatisfiable

2. find variables which only occur in one phase (only positive or negative)

3. remove all clauses in which these variables occur

4. if no clause left then terminate with result satisfiable

5. choose $x$ as one of the remaining variables with occurrences in both phases

6. add results of all possible resolutions on this variable

7. remove all trivial clauses and all clauses in which $x$ occurs

8. continue with 1.
check whether XOR is weaker than OR, i.e. validity of:

\[ a \lor b \rightarrow (a \oplus b) \]

which is equivalent to unsatisfiability of the negation:

\[ (a \lor b) \land \neg (a \oplus b) \]

since negation of XOR is XNOR (equivalence):

\[ (a \lor b) \land (a \leftrightarrow b) \]

we end up checking the following CNF for satisfiability:

\[ (a \lor b) \land (\neg a \lor b) \land (a \lor \neg b) \]
$$(a \lor b) \land (\neg a \lor b) \land (a \lor \neg b)$$

Initially we can skip 1. - 4. of the algorithm and choose $x = b$ in 5.

In 6. we resolve $$(\neg a \lor b)$$ with $$(a \lor \neg b)$$ and $$(a \lor b)$$ with $$(a \lor \neg b)$$ both on $b$

and add the results $$(a \lor \neg a)$$ and $$(a \lor a)$$:

$$(a \lor b) \land (\neg a \lor b) \land (a \lor \neg b) \land (a \lor \neg a) \land (a \lor a)$$

The trivial clause $$(a \lor \neg a)$$ and clauses with occurrences of $b$ are removed:

$$(a \lor a)$$

In 2. we find $a$ to occur only positive and in 3. the remaining clause is removed

The test in 4. succeeds and the CNF turns out to be satisfiable

(Thus the original formula is invalid – not a tautology)
**Proof.** in three steps:

(A) show that termination criteria are correct

(B) each transformation preserves satisfiability

(C) each transformation preserves unsatisfiability

Ad (A):

an empty clause is an empty disjunction, which is unsatisfiable

if literals occur only in one phase assign those to 1 ⇒ all clauses satisfied
**CNF transformations preserve satisfiability:**

removing a clause does not change satisfiability

thus only adding clauses could potentially not preserve satisfiability

the only clauses added are the results of resolution

correctness of resolution rule shows:

if the original CNF is satisfiable, then the added clause are satisfiable

(even with the same satisfying assignment)
CNF transformations preserve unsatisfiability:

adding a clause does not change unsatisfiability

thus only removing clauses could potentially not preserve unsatisfiability

trivial clauses \((v \lor \neg v \lor \ldots)\) are always valid and can be removed

let \(f\) be the CNF after removing all trivial clauses (in step 7.)

let \(g\) be the CNF after removing all clauses in which \(x\) occurs (after step 7.)

we need to show \((f \text{ unsat} \Rightarrow g \text{ unsat})\), or equivalently \((g \text{ sat} \Rightarrow f \text{ sat})\)

the latter can be proven as the completeness proof for the resolution rule
(see next slide)
If we interpret $\cup$ as disjunction and clauses as formulae, then

$$(C_1 \vee x) \land \ldots \land (C_k \vee x) \land (D_1 \vee \neg x) \land \ldots \land (D_l \vee \neg x)$$

is, via distributivity law, equivalent to

$$((C_1 \land \ldots \land C_k) \vee x) \land ((D_1 \land \ldots \land D_l) \vee \neg x)$$

and the same proof applies as for the completeness of the resolution rule.

**Note:** just using the completeness of the resolution rule alone does not work, since those $\sigma'$ derived for multiple resolutions are formally allowed to assign different values for the resolution variable.
Problems with DP

- if variables have many occurrences, then many resolutions are necessary
- in the worst case, \( x \) and \( \neg x \) occur in half of the clauses ...
- ... then the number of clauses increases quadratically
- clauses become longer and longer
- unfortunately in real world examples the CNF explodes

**How to obtain the satisfying assignment efficiently (counter example)?**
- resolution based version often called DP, second version DPLL (DP after [DavisPutnam60] and DPLL after [DavisLogemannLoveland62])
- it eliminates variables through case analysis: time vs space
- only unit resolution used (also called boolean constraint propagation)
- case analysis is on-the-fly:
  - cases are not elaborated in a predefined fixed order, but ...
  - … only remaining crucial cases have to be considered
- allows sophisticated optimizations
a **unit clause** is a clause with a single literal

in CNF a unit clause forces its literal to be assigned to 1

**unit resolution** is an application of resolution, where one clause is a unit clause

also called *boolean constraint propagation*

**Unit-Resolution Rule**

\[
C \cup \{ \neg l \} \quad \{ l \} \\
\hline
\{ l, \neg l \} \cap C = \emptyset \\
C
\]

here we identify \( \neg \neg v \) with \( v \) for all variables \( v \).
check whether XNOR is weaker than AND, i.e. validity of:

\[ a \land b \rightarrow (a \leftrightarrow b) \]

which is equivalent to unsatisfiability of the CNF (exercise)

\[ a \land b \land (a \lor b) \land (\neg a \lor \neg b) \]

adding clause obtained from unit resolution on \( a \) results in

\[ a \land b \land (a \lor b) \land (\neg a \lor \neg b) \land (\neg b) \]

removing clauses containing \( a \) or \( \neg a \)

\[ b \land (\neg b) \]

unit resolution on \( b \) results in an empty clause and we conclude unsatisfiability.
- if unit resolution produces a unit, e.g. resolving \((a \lor \neg b)\) with \(b\) produces \(a\), continue
  unit resolution with this new unit
- often this repeated application of unit resolution is also called unit resolution
- unit resolution + removal of subsumed clauses never increases size of CNF

\[
C \text{ subsumes } D \iff C \subseteq D
\]

a unit(-clause) \(l\) subsumes all clauses in which \(l\) occurs in the same phase

- **boolean constraint propagation** (BCP): given a unit \(l\), remove all clauses in which \(l\) occurs in the same phase, and remove all literals \(\neg l\) in clauses, where it occurs in the opposite phase (the latter is unit resolution)
Basic DPLL Algorithm

1. apply repeated unit resolution and removal of all subsumed clauses (BCP)

2. if empty clause found then return unsatisfiable

3. find variables which only occur in one phase (only positive or negative)

4. remove all clauses in which these variables occur (pure literal rule)

5. if no clause left then return satisfiable

6. choose $x$ as one of the remaining variables with occurrences in both phases

7. recursively call DPLL on current CNF with the unit clause \{$x$\} added

8. recursively call DPLL on current CNF with the unit clause \{$\neg x$\} added

9. if one of the recursive calls returns satisfiable return satisfiable

10. otherwise return unsatisfiable
DPLL Example

\[(\neg a \lor b) \land (a \lor \neg b) \land (\neg a \lor \neg b)\]

Skip 1. - 6., and choose \(x = a\). First recursive call:

\[(\neg a \lor b) \land (a \lor \neg b) \land (\neg a \lor \neg b) \land a\]

unit resolution on \(a\) and removal of subsumed clauses gives

\[b \land (\neg b)\]

BCP gives empty clause, return unsatisfiable. Second recursive call:

\[(\neg a \lor b) \land (a \lor \neg b) \land (\neg a \lor \neg b) \land \neg a\]

BCP gives \(\neg b\), only positive recurrence of \(b\) left, return satisfiable

(satisfying assignment \(\{a \mapsto 0, b \mapsto 0\}\))
Expansion Theorem of Shannon

**Theorem.**

\[ f(x) \equiv x \land f(1) \lor \bar{x} \land f(0) \]

**Proof.**

Let \( \sigma \) be an arbitrary assignment to variables in \( f \) including \( x \)

**case** \( \sigma(x) = 0 \):

\[ \sigma(f(x)) = \sigma(f(0)) = \sigma(0 \land f(1) \lor 1 \land f(0)) = \sigma(x \land f(1) \lor \bar{x} \land f(0)) \]

**case** \( \sigma(x) = 1 \):

\[ \sigma(f(x)) = \sigma(f(1)) = \sigma(1 \land f(1) \lor 0 \land f(0)) = \sigma(x \land f(1) \lor \bar{x} \land f(0)) \]
first observe: \( x \land f(x) \) is satisfiable \iff \( x \land f(1) \) is satisfiable

similarly, \( \overline{x} \land f(x) \) is satisfiable \iff \( \overline{x} \land f(0) \) is satisfiable

then use expansion theorem of Shannon:

\[
f(x) \text{ satisfiable} \iff \overline{x} \land f(0) \text{ or } x \land f(1) \text{ satisfiable} \iff \overline{x} \land f(x) \text{ or } x \land f(x) \text{ satisfiable}
\]

rest follows along the lines of the the correctness proof for resolution based DP
- each variable is marked as unassigned, false, or true \(\{X, 0, 1\}\)

- no explicit resolution:
  - when a literal is assigned visit all clauses where its negation occurs
  - find those clauses which have all but one literal assigned to false
  - assign remaining non false literal to true and continue

- decision:
  - heuristically find a variable that is still unassigned
  - heuristically determine phase for assignment of this variable
- **decision level** is the depth of recursive calls (= #nested decisions)
- the **trail** is a stack to remember order in which variables are assigned
- for each decision level the old trail height is saved on the control stack
- undoing assignments in backtracking:
  - get old trail height from control stack
  - unassign all variables up to the old trail height

Example cont.

BCP

Decision level

Control

Trail

Variables

Assignment

Clauses

\begin{itemize}
    \item BCP
    \item Decision level
    \item Control
    \item Trail
    \item Variables
    \item Assignment
    \item Clauses
\end{itemize}
**static heuristics:**
- one *linear* order determined before solver is started
- usually quite fast, since only calculated once
- can also use more expensive algorithms

**dynamic heuristics**
- typically calculated from number of occurrences of literals (in unsatisfied clauses)
- rather expensive, since it requires traversal of all clauses (or more expensive updates in BCP)
- recently, *second order* dynamic heuristics (VSIDS in Chaff ⇒ *see learning*)
- view CNF as a graph:
  - clauses as nodes, edges between clauses with same variable

- a *cut* is a set of variables that splits the graph in two parts

- recursively find short cuts that cut of parts of the graph

- static or dynamically order variables according to the cuts

```
-2 1 -3 1 -1 2 3 -4 3 1, 2, -1, -2
assume
no occurences of
on the right side
short cut
```

assume no occurrences of 1, 2, -1, -2 on the right side
```c
int
sat (CNF cnf)
{
  SetOfVariables cut = generate_good_cut (cnf);
  CNF assignment, left, right;

  left = cut_off_left_part (cut, cnf);
  right = cut_off_right_part (cut, cnf);

  forall_assignments (assignment, cut)
  {
    if (sat (apply (assignment, left)) && sat (apply (assignment, right)))
      return 1;
  }

  return 0;
}
```
- resembles cuts in circuits when CNF is generated with Tseitin transformation
- ideally cuts have constant or logarithmic size …
  - for instance in tree-like circuits
  - so the problem is *reconvergence*:
    - the same signal / variable is used multiple times
- … then satisfiability actually becomes polynomial (see exercise)
A clause is called \textit{positive} if it contains a positive literal.

A clause is called \textit{negative} if all its literals are negative.

A clause is a \textit{Horn} clause if contains at most one positive literal.

CNF is in \textit{Horn Form} iff all clauses are Horn clause (Prolog without negation)

Order assignments point-wise: \( \sigma \leq \sigma' \) iff \( \sigma(x) \leq \sigma'(x) \) for all \( x \in V \)

Horn Form with only positive clauses has minimal satisfying assignment.

Minimal satisfying assignment is obtained by BCP (polynomial).

A Horn Form is satisfiable iff the minimal assignments of its positive part satisfies all its negative clauses as well.
- CNF in Horn Form: use above specialized fast algorithm
- non Horn: split on literals which occurs positive in non Horn clauses
  - actually choose variable which occurs most often in such clauses
- this gradually transforms non Horn CNF into Horn Form
- main heuristic in SAT solver SATO

**Note:** In general, BCP in DP prunes search space by avoiding assignments incompatible to minimal satisfying assignment for the Horn part of the CNF.

| non Horn part of CNF | Horn part of CNF |
Other popular Decision Heuristics

- **Dynamic Largest Individual Sum (DLIS)**
  - fastest dynamic first order heuristic (e.g. GRASP solver)
  - choose literal (variable + phase) which occurs most often
  - ignore satisfied clauses
  - requires explicit traversal of CNF (or more expensive BCP)

- **look-forward heuristics** (e.g. SATZ or MARCH solver)  
  - failed literals, probing
  - do trial assignments and BCP for all unassigned variables (both phases)
  - if BCP leads to conflict, force toggled assignment of current trial decision
  - skip trial assignments implied by previous trial assignments
    (removes a factor of $|V|$ from the runtime of one decision search)
  - decision variable maximizes number of propagated assignments
Reducing Learned Clauses

- keeping all learned clauses slows down BCP
  - so SATO and RelSAT just kept only “short” clauses
- better periodically delete “useless” learned clauses
  - keep a certain number of learned clauses
  - if this number is reached MiniSAT reduces (deletes) half of the clauses
  - keep most active, then shortest, then youngest (LILO) clauses
  - after reduction maximum number kept learned clauses is increased geometrically
- LBD (Glue) based (apriori!) prediction for usefulness
  - LBD (Glue) = number of decision-levels in the learned clause
  - allows arithmetic increase of number of kept learned clauses
  - keep clauses with small LBD forever ($\leq 2 \ldots 5$)
  - large fixed cache useful for hard satisfiable instances (crypto)

[LaudemardLaurent’09]
[Chanseok Oh]
- for satisfiable instances the solver may get stuck in the unsatisfiable part
  - even if the search space contains a large satisfiable part

- often it is a good strategy to abandon the current search and restart
  - restart after the number of decisions reached a *restart limit*

- avoid to run into the same dead end
  - by randomization (either on the decision variable or its phase)
  - and/or just keep all the learned clauses

- for completeness dynamically increase restart limit
  - arithmetically, geometrically, Luby, Inner/Outer
  - recent technique from Glucose:
    - short vs. large window running average LBD
    - if recent LBD values are larger than long time average then restart
378 restarts in 104408 conflicts
int inner = 100, outer = 100;
int restarts = 0, conflicts = 0;

for (;;)
{
    ... // run SAT core loop for 'inner' conflicts

    restarts++;
    conflicts += inner;

    if (inner >= outer)
    {
        outer *= 1.1;
        inner = 100;
    }
    else
        inner *= 1.1;
}
Luby’s Restart Intervals

70 restarts in 104448 conflicts
unsigned
luby (unsigned i)
{
    unsigned k;

    for (k = 1; k < 32; k++)
        if (i == (1 << k) - 1)
            return 1 << (k - 1);

    for (k = 1;; k++)
        if ((1 << (k - 1)) <= i && i < (1 << k) - 1)
            return luby (i - (1 << (k-1)) + 1);
}

limit = 512 * luby (++restarts);
... // run SAT core loop for 'limit' conflicts
Reluctant Doubling Sequence

[Knuth’15]

\[(u_1, v_1) := (1, 1)\]

\[(u_{n+1}, v_{n+1}) := (u_n \& -u_n = v_n \? (u_n + 1, 1) : (u_n, 2v_n))\]

\[(1, 1), (2, 1), (2, 2), (3, 1), (4, 1), (4, 2), (4, 4), (5, 1), \ldots\]
phase assignment:
  - assign decision variable to 0 or 1?
  - the only thing that matters in satisfiable instances

“phase saving” as in RSat:
  - pick phase of last assignment (if not forced to, do not toggle assignment)
  - initially use statically computed phase (typically LIS)

rapid restarts: varying restart interval with bursts of restarts
  - not only theoretically avoids local minima
  - works nicely together with phase saving
Exponential Moving Average Restart Scheduling

- **LBD**
  - fast EMA of LBD with $\alpha = 2^{-5}$
- **restart**
  - slow EMA of LBD with $\alpha = 2^{-14}$ (ema-14)
- **inprocessing**
  - CMA of LBD (average)
If $y$ has never been used to derive a conflict, then skip $\overline{y}$ case.

Immediately *jump back* to the $\overline{x}$ case – assuming $x$ was used.
Backjumping Example

Split on $-3$ first (bad decision).
Split on $-1$ and get first conflict.
Regularly backtrack and assign 1 to get second conflict.
Backjumping Example

Backtrack to root, assign 3 and derive same conflicts.
Assignment \(-3\) does not contribute to conflict.
Backjumping Example

So just *backjump* to root before assigning 1.
- backjumping helps to *recover* from bad decisions
  - bad decisions are those that do not contribute to conflicts
  - without backjumping same conflicts are generated in second branch
  - with backjumping the second branch of bad decisions is just skipped

- particularly useful for unsatisfiable instances
  - in satisfiable instances good decisions will guide us to the solution

- with backjumping many bad decisions increase search space roughly quadratically instead of exponentially with the number of bad decisions
the implication graph maps inputs to the result of resolutions

backward from the empty clause all contributing clauses can be found

the variables in the contributing clauses are contributing to the conflict

important optimization, since we only use unit resolution
- generate graph only for resolutions that result in unit clauses
- the assignment of a variable is result of a decision or a unit resolution
- therefore the graph can be represented by saving the reasons for assignments with each assigned variable
(edges of directed hyper graphs may have multiple source and target nodes)
- graph becomes an ordinary (non hyper) directed graph
- simplifies implementation:
  - store a pointer to the reason clause with each assigned variable
  - decision variables just have a null pointer as reason
  - decisions are the roots of the graph
- can we learn more from a conflict?
  - backjumping does not fully avoid the occurrence of the same conflict
  - the same (partial) assignments may generate the same conflict
- generate conflict clauses and add them to CNF
  - the literals contributing to a conflict form a partial assignment
  - this partial assignment is just a conjunction of literals
  - its negation is a clause (implied by the original CNF)
  - adding this clause avoids this partial assignment to happen again
observation: current decision always contributes to conflict
- otherwise BCP would have generated conflict one decision level lower
- conflict clause has (exactly one) literal assigned on current decision level

instead of backtracking
- generate and add conflict clause
- undo assignments as long conflict clause is empty or unit clause (in case conflict clause is the empty clause conclude unsatisfiability)
- resulting assignment from unit clause is called *conflict driven assignment*

We use a version of the DIMACS format.

Variables are represented as positive integers.

Integers represent literals.

Subtraction means negation.

A clause is a zero terminated list of integers.

CNF has a good cut made of variables 3 and 4 (cf Exercise 4 + 5).

(but we are going to apply DP with learning to it)
Run 1 (3 as 1st decision)

\[ l = 0 \] (no unit clause originally, so no implications)

\[ l = 1 \]

unit clause \(-3\) is generated as learned clause and we backtrack to \( l = 0 \)

since \(-3\) has a real unit clause as reason, an empty conflict clause is learned.
Run 2 Fig. 1 (-1, 3 as decision order)

\[ l = 0 \]
(no unit clause originally, so no implications)

\[ l = 1 \]
(no implications on this decision level either)

\[ l = 2 \]
(using the FIRST clause)

since FIRST clause was used to derive 2, conflict clause is (1 −3)

backtrack to \( l = 1 \) (smallest level for which conflict clause is a unit clause)
Run 2 Fig. 2 (-1, 3 as decision order)

\[ l = 0 \] (no unit clause originally, so no implications)

\[ l = 1 \]

\[ \text{1st conflict clause} \]

\[ \text{learned conflict clause is the unit clause 1} \]

\[ \text{backtrack to decision level } l = 0 \]
since the learned clause is the empty clause, conclude unsatisfiability
Run 3 Fig. 1 (-6, 3 as decision order)

\[ l = 0 \] (no unit clause originally, so no implications)

\[ l = 1 \] \(-6\) (no implications on this decision level either)

\[ l = 2 \]

\[ \square \]

learn the unit clause \(-3\) and BACKJUMP to decision level \( l = 0 \)
Run 3 Fig. 1 (-6, 3 as decision order)

finally the empty clause is derived which proves unsatisfiability
```c
int
sat (Solver solver)
{
    Clause conflict;

    for (;;)
    {
        if (bcp_queue_is_empty (solver) && !decide (solver))
            return SATISFIABLE;

        conflict = deduce (solver);

        if (conflict && !backtrack (solver, conflict))
            return UNSATISFIABLE;
    }
}
```
int backtrack (Solver solver, Clause conflict)
{
    Clause learned_clause; Assignment assignment; int new_level;

    if (decision_level(solver) == 0)
        return 0;

    analyze (solver, conflict);
    learned_clause = add (solver);

    assignment = drive (solver, learned_clause);
    enqueue_bcp_queue (solver, assignment);

    new_level = jump (solver, learned_clause);
    undo (solver, new_level);

    return 1;
}
conflict clause: obtained by backward resolving empty clause with reasons
  - start at clause which has all its literals assigned to false
  - resolve one of the false literals with its reason
  - invariant: result still has all its literals assigned to false
  - continue until user defined size is reached

- gives a nice correspondence between resolution and learning in DP
  - allows to generate a resolution proof from a DP run
  - implemented in RELSAT solver [BayardoSchrag'97]
a simple cut always exists: set of roots (decisions) contributing to the conflict
UIP = *articulation point* in graph decomposition into biconnected components (simply a node which, if removed, would disconnect two parts of the graph)
can be found by graph traversal in the order of made assignments

- trail respects this order
- traverse reasons of variables on trail starting with conflict
- count “open paths”
  (initially size of clause with only false literals)
- if all paths converged at one node, then UIP is found
- decision of current decision level is a UIP and thus a sentinel
- assume a non decision UIP is found
- this UIP is part of a potential cut
- graph traversal may stop (everything *behind* the UIP is ignored)
- negation of the UIP literal constitutes the conflict driven assignment
- may start new clause generation (UIP replaces conflict)
  - each conflict may generate multiple learned clauses
  - however, using only the first UIP encountered seems to work best
1st UIP learned clause increases chance of backjumping
(“pulls in” as few decision levels as possible)
- intuitively it is important to localize the search (cf cutwidth heuristics)
- cuts for learned clauses may only include UIPs of current decision level
- on lower decision levels an arbitrary cut can be chosen
- multiple alternatives
  - include all the roots contributing to the conflict
  - find minimal cut (heuristically)
  - cut off at first literal of lower decision level  (works best)
\[ d \wedge g \wedge s \rightarrow t \quad \equiv \quad (\bar{d} \vee \bar{g} \vee \bar{s} \vee t) \]
\[ \neg (y \land z) \equiv (\overline{y} \lor \overline{z}) \]

\end{align*}
\]
Locally Minimized Learned Clause

\[(d \lor g \lor \overline{s} \lor \overline{h})\]
Two step algorithm:

1. mark all variables in 1st UIP clause

2. remove literals with all antecedent literals also marked

Correctness:
- removal of literals in step 2 are self subsuming resolution steps.
- implication graph is acyclic.

Confluence: produces a unique result.
Recursively Minimizing Learned Clause

Decision Procedures and SMT #342.255 WS 2016/2017 Armin Biere, Martina Seidl JKU Linz
Recursively Minimized Learned Clause

\[(d \lor \overline{g} \lor \overline{s})\]
Recursive Minimization Algorithm

[MiniSAT 1.13]

Four step algorithm:

1. mark all variables in 1st UIP clause

2. for each candidate literal: search implication graph

3. start at antecedents of candidate literals

4. if search always terminates at marked literals remove candidate

Correctness and Confluence as in local version!!!

Optimization: terminate early with failure if new decision level is “pulled in”

</table>
Zero order scheme = static scores
- computed for instance once during preprocessing
- still needs search for “best” unassigned variable
- only total orders considered so far

First order schemes = dynamic but stateless
- for instance: score = pos occs × neg occs
- independent of how search reached current branch / search node
- might be quite expensive to compute / update (linear in CNF size)

Second order schemes: variable score depends on history of search
- first order + learning ⇒ second order
- but can also be used to speed up search for “best” variable
- goal is logarithmic or even constant algorithm for variable selection
“second order” because it involves statistics about the search

Variable State Independent Decaying Sum (VSIDS) decision heuristic (implemented in Chaff, Limmat, MiniSAT, PicoSAT, and many more)

VSIDS just counts the occurrences of literals in conflict clauses

literal/variable with maximal count (score) is chosen (from a priority queue ordered by score)

score is multiple by a factor $f < 1$ after a certain number of conflicts occurred (this is the “decaying” part and also called rescoreing)

emphasizes (negation of) literals contributing recently to conflicts (localization)
Normalized VSIDS: NVSIDS

[Biere-SAT’08]

- VSIDS score can be normalized to the interval [0,1] as follows:
  - pick a decay factor $f$ per conflict: typically $f = 0.95$
  - each variable is punished by this decay factor at every conflict
  - if a variable is involved in conflict, add $1 - f$ to score

\[
s, f \leq 1, \quad \text{then} \quad s' \leq s \cdot f + 1 - f \leq f + 1 - f = 1
\]

with $s$ old score before conflict, $s'$ new score after conflict

- recomputing score of all variables at each conflict is costly
  - linear in the number of variables, e.g. millions
  - particularly, because number of involved variables << number of variables
Exponential VSIDS: EVSIDS

- Chaff: precision of score traded for faster decay
  - increment score of involved variables by 1
  - decay score of all variables every 256 conflicts by halving the score
  - sort priority queue after decay and not at every conflict

- MiniSAT uses Exponential VSIDS
  - also just update score of involved variables
  - dynamically adjust increment: \( \delta' = \delta \cdot \frac{1}{f} \) (typically increment \( \delta \) by 5%)
  - use floating point representation of score
  - “rescore” to avoid overflow in regular intervals
  - EVSIDS linearly related to NVSIDS
Relating EVSIDS and NVSIDS

consider again only one variable with score sequence $s_n$ resp. $S_n$

$$\delta_k = \begin{cases} 1 & \text{if involved in } k\text{-th conflict} \\ 0 & \text{otherwise} \end{cases}$$

$$i_k = (1 - f) \cdot \delta_k$$

$$s_n = (\ldots (i_1 \cdot f + i_2) \cdot f + i_3) \cdot f \ldots ) \cdot f + i_n = \sum_{k=1}^{n} i_k \cdot f^{n-k} = (1 - f) \cdot \sum_{k=1}^{n} \delta_k \cdot f^{n-k} \quad \text{(NVSIDS)}$$

$$S_n = \frac{f^n}{(1 - f)} \cdot s_n = \frac{f^n}{(1 - f)} \cdot (1 - f) \cdot \sum_{k=1}^{n} \delta_k \cdot f^{n-k} = \sum_{k=1}^{n} \delta_k \cdot f^{-k} \quad \text{(EVSIDS)}$$
observation:
- recently added conflict clauses contain all the good variables of VSIDS
- the order of those clauses is not used in VSIDS

basic idea:
- simply try to satisfy recently learned clauses first
- use VSIDS to chose the decision variable for one clause
- if all learned clauses are satisfied use other heuristics
- intuitively obtains another order of localization (no proofs yet)

results are mixed (by some authors considered to be more robust than just VSIDS)
Other Variable Scoring Variants

- **variable move to front strategy (VMTF)**
  - Siege SAT Solver [Ryan’04]
  - easy and cheap to implement with doubly linked list
    - need pointer to last picked variable in queue
    - reset during back-tracking
  - rather aggressive

- **clause move to front strategy (CMTF)**
  - HaifaSAT [GershanStrichman’08] variant keeps clauses in a queue
  - queue can also be used to find less important clauses to throw away
  - refined version in PrecoSAT [Biere’09] (multiple queues per glucose level)
### Variable Scoring Schemes

$0 < f < 1 \quad g = 1/f \quad h_i^m = 0.5 \quad$ if $m$ divides $i \quad h_i^m = 1$ otherwise

$i$ conflict index $b$ bumped counter
Fast VMTF Implementation

- fast simple implementation for caching searches in VMTF [Biere'15]
  - doubly linked list does not have positions as an ordered array
  - $\text{bump} = \text{move-to-front} = \text{dequeue}$ then $\text{insertion}$ at the head
- time-stamp list entries with insertion time
  - maintained invariant: all variables right of next-search are assigned
  - requires update to next-search while unassigning variables

![Diagram showing the process of caching searches in VMTF with time-stamps and variable assignments]
should not keep all learned clauses forever
  some of them become useless
  for instance subsumed or satisfied under learned units
  were but are not anymore relevant to current search focus
  memory consumption / BCP speed
  throw *unimportant* learned clauses away (reduce)
  in regular intervals (controlled by geometric, Luby, arithmetic scheme)
  *size* heuristics: discard long clauses
  *least recently used* (LRU): as in HW cache (see also CMTF)
  clause scores with bumping scheme as for VSDIS (BerkMin)
  glucose level: number decision levels in learned clause
called also LBD in original paper [AudemardLaurentSimon’09]

Decision Procedures and SMT  #342.255  WS 2016/2017
Armin Biere, Martina Seidl  JKU Linz
Average Number Clauses Visited Per Propagation
Average Learned Clause Length
invariant: first two literals are watched
invariant: first two literals are watched
Additional Binary Clause Watcher Stack
observation: often the other watched literal satisfies the clause

so cache this literals in watch list to avoid pointer dereference

for binary clause no need to store clause at all

can easily be adjusted for ternary clauses (with full occurrence lists)

LINGELING uses more compact pointer-less variant
similar to look-ahead heuristics: polynomials bounded search
  may be recursively applied (however, is often too expensive)

Stålmarck’s Method
  works on triplets (intermediate form of the Tseitin transformation):
  \[ x = (a \land b), \quad y = (c \lor d), \quad z = (e \oplus f) \] etc.
  generalization of BCP to (in)equalities between variables
  test rule splits on the two values of a variable

Recursive Learning (Kunz & Pradhan)
  (originally) works on circuit structure (derives implications)
  splits on different ways to justify a certain variable value
1. BCP over (in)equalities: \[ \frac{x = y}{z = 0} \quad \frac{z = (x \oplus y)}{z = 0} \quad \frac{x = 0}{z = (x \lor y)} \quad \frac{z = y}{\text{etc.}} \]

2. Structural rules: \[ \frac{x = (a \lor b)}{y = (a \lor b)} \quad \frac{x = y}{\text{etc.}} \]

3. Test rule:

\[
\begin{array}{c}
\{x = 0\} \cup E \\
\downarrow \\
E_0 \cup E
\end{array}
\quad
\begin{array}{c}
\{x = 1\} \cup E \\
\downarrow \\
E_1 \cup E
\end{array}
\]

\[
\frac{(E_0 \cap E_1) \cup E}{(E_0 \cup E) \cup (E_1 \cup E)}
\]

Assume \( x = 0 \), BCP and derive (in)equalities \( E_0 \), then assume \( x = 1 \), BCP and derive (in)equalities \( E_1 \). The intersection of \( E_0 \) and \( E_1 \) contains the (in)equalities valid in \textit{any} case.
Stålmarck’s Method Recursively

\[ x = 0 \]
\[ \downarrow \]
\[ y = 0 \quad y = 1 \]
\[ \downarrow \quad \downarrow \]
\[ E_{00} \quad E_{01} \]

\[ E_{0} \]

\[ x = 1 \]
\[ \downarrow \]
\[ y = 0 \quad y = 1 \]
\[ \downarrow \quad \downarrow \]
\[ E_{10} \quad E_{11} \]

\[ E_{1} \]

\[ E \]

(we do not show the (in)equalities that do not change)
Stålmarck’s Method Summary

- recursive application
  - depth of recursion bounded by number of variables
  - complete procedures (determines satisfiability or unsatisfiability)
  - for a fixed (constant) recursion depth $k$ polynomial!

- $k$-saturation:
  - apply split rule on recursively up to depth $k$ on all variables
  - 0-saturation: apply all rules except test rule (just BCP: linear)
  - 1-saturation: apply test rule (not recursively) for all variables (until no new (in)equalities can be derived)
circuits

output 0 implies middle input 0 indirectly

- CNF
  - for each clause $c$ in the CNF
    - for each literal $l$ in the clause $c$
      - assume $l$ and propagate
      - collect set of all implied literals (direct/indirect “implications” of $l$)
    - intersect these sets of implied literals over all $l$ in $c$
    - literals in the intersection are implied without any assumption
Bounded Variable Elimination (BVE)

- use DP to existentially quantify out variables as in [DavisPutnam60]
- only remove a variable if this does not add (too many) clauses
  - do not count tautological resolvents
  - detect units on-the-fly
- schedule removal attempts with a priority queue
  - variables ordered by the number of occurrences
- strengthen and remove subsumed clauses (on-the-fly)
  (SATeLite [EénBiere SAT’05] and Quantor [Biere SAT’04])
Fast (Self) Subsumption

- for each (new or strengthened) clause
  - traverse list of clauses of the least occurring literal in the clause
  - check whether traversed clauses are subsumed or
  - strengthen traversed clauses by self-subsumption [EénBiere SAT’05]
  - use Bloom Filters (as in “bit-state hashing”), aka signatures

- checking new clauses against existing clauses: backward (self) subsumption
  - new clause (self) subsumes existing clause
  - new clause smaller or equal in size

- check clause being subsumed by existing clauses forward (self) subsumption
  - can be made more efficient by one-watcher scheme [Zhang-SAT’05]
for all iterals $l$
  - for all clauses $c$ in which $l$ occurs (with this particular phase)
    - assume the negation of all the other literals in $c$, assume $l$
    - if BCP does not lead to a conflict continue with next literal in outer loop
  - if all clauses produced a conflict permanently assign $\neg l$

**Correctness:** Let $c = l \lor d$, assume $\neg d \land l$.

If this leads to a conflict $d \lor \neg l$ could be learned (but is not added to the CNF).

Self subsuming resolution with $c$ results in $d$ and $c$ is removed.

If all such cases lead to a conflict, $\neg l$ becomes a pure literal.
Generalization of pure literals.

Given a partial assignment \( \sigma \).

A clause of a CNF is “touched” by \( \sigma \) if it contains a literal assigned by \( \sigma \).

A clause of a CNF is “satisfied” by \( \sigma \) if it contains a literal assigned to true by \( \sigma \).

If all touched clauses are satisfied then \( \sigma \) is an “autarky”.

All clauses touched by an autarky can be removed.

Example: \((-1\ 2)(-1\ 3)(1\ -2\ -3)(2\ 5)\cdots \) (more clauses without 1 and 3).

Then \( \sigma = \{-1, -3\} \) is an autarky.
Blocked Clauses

[Kullman’99]

-blocked clause $C \in F$ all clauses in $F$ with $\bar{l}$

-fix a CNF $F$

$$(\bar{l} \lor \bar{a} \lor c)$$

$$(a \lor b \lor l)$$

$$(\bar{l} \lor \bar{b} \lor d)$$

since all resolvents of $C$ on $l$ are tautological $C$ can be removed

**Proof** assume assignment $\sigma$ satisfies $F \setminus C$ but not $C$

can be extended to a satisfying assignment of $F$ by flipping value of $l$

Tseitin encoding
equivalent literal substitution  find strongly connected components in binary implication graph, replace equivalent literals by representatives

boolean ring reasoning  extract XORs, then Gaussian elimination etc.

hyper-binary resolution  focus on producing binary resolvents

hidden/asymmetric tautology elimination  discover redundant clauses through probing

covered clause elimination  use covered literals in probing for redundant clauses

unhiding  randomized algorithm (one phase linear) for clause removal and strengthening
PrecoSAT [Biere’09], Lingeling [Biere’10], also in CryptoMiniSAT (Mate Soos)

- preprocessing can be extremely beneficial
  - most SAT competition solvers use bounded variable elimination (BVE) [EénBiere SAT’05]
  - equivalence / XOR reasoning
  - probing / failed literal preprocessing / hyper binary resolution
  - however, even though polynomial, can not be run until completion

- simple idea to benefit from full preprocessing without penalty
  - “preempt” preprocessors after some time
  - resume preprocessing between restarts
  - limit preprocessing time in relation to search time
Benefits of Inprocessing

- special case *incremental preprocessing*:
  - preprocessing during incremental SAT solving
- allows to use *costly* preprocessors
  - without increasing run-time “much” in the worst-case
  - still useful for benchmarks where these costly techniques help
  - good examples: probing and distillation

- additional benefit:
  - makes units / equivalences learned in search available to preprocessing
  - particularly interesting if preprocessing simulates encoding optimizations
- danger of hiding “bad” implementation though …
- … and hard(er) to debug and get right
