# Pragmatics

We will now investigate the **pragmatics** (practical use) of first-order logic in two contexts.

## ■ Defining Models

- Introducing new domains and operations.
- Unique characterizations of their meaning.

## ■ Specifying Problems

- Describing expectations for computations.
- Assumptions on the inputs and guarantees for the outputs.

Highly relevant for computer science and mathematics.

## Standard Models

We assume the following “standard models” as given.

**Natural Numbers**  $\mathbb{N} = \{0, 1, 2, \dots\}$ ,  $\mathbb{N}_n = \{0, \dots, n-1\}$ ,  $\mathbb{N}_{>0} = \{1, 2, \dots\}$ , etc.

**Integer Numbers**  $\mathbb{Z} = \{\dots, -2, -1, 0, 1, 2, \dots\}$ .

**Real Numbers**  $\mathbb{R}$ ,  $\mathbb{R}_{\geq 0}$ ,  $\mathbb{R}_{>0}$ .

- Usual arithmetic operations for all number domains.

**Sets**  $\mathcal{P}(T)$ : all sets with elements of set  $T$ .

- Element predicate  $e \in S$ , set builder term  $\{t \mid x \in S \wedge \dots \wedge F\}$ .

**Products**  $T_1 \times \dots \times T_n$ : all tuples  $(c_1, \dots, c_n)$  with components from  $T_1, \dots, T_n$ .

- For  $t = (c_1, \dots, c_n)$  we have  $t.1 = c_1, \dots, t.n = c_n$ .

**Sequences**  $T^*$ : all finite sequences with values from  $T$ ;  $T^\omega$ : all infinite sequences.

- $s \in T^* : s = [s(0), s(1), s(2), \dots, s(n-1)]$ ,  $\text{length}(s) = n$ .

The “builtin data types” of our models.

## Domain Definitions

From the standard domains, we may build new domains.

- A domain definition

$$T := t$$

defines a new domain  $T$  from a term  $t$  that denotes a set (constructed from previous sets by the application of set builders and/or domain constructors).

$$\text{Nat} := \mathbb{N}_{2^{32}}$$

$$\text{Int} := \{i \mid i \in \mathbb{Z} \wedge -2^{31} \leq i \wedge i < 2^{31}\}$$

$$\text{IntArray} := \text{Int}^*$$

$$\text{IntStream} := \text{Int}^\omega$$

$$\text{Primes} := \{x \mid x \in \mathbb{N} \wedge x \geq 2 \wedge (\forall y \in \mathbb{N} : 1 < y \wedge y < x \rightarrow \neg(y|x))\}$$

# Explicit Function Definitions

A new function may be introduced by describing its value.

■ An **explicit function definition**

$$f: T_1 \times \dots \times T_n \rightarrow T$$

$$f(x_1, \dots, x_n) := t_x$$

- introduces a new  $n$ -ary **function symbol**  $f$  with
- a **type signature**  $T_1 \times \dots \times T_n \rightarrow T$  with sets  $T_1, \dots, T_n, T$ ,
- a list of variables  $x_1, \dots, x_n$  (the **parameters**), and
- a term  $t_x$  (the **body**) whose free variables occur in  $x_1, \dots, x_n$ ;
- case  $n = 0$ : the definition of a constant  $f: T, f := t$ .

■ We have to show  $(\forall x_1 \in T_1, \dots, x_n \in T_n: t_x \in T)$  and then know

$$\forall x_1 \in T_1, \dots, x_n \in T_n: f(x_1, \dots, x_n) = t_x$$

The body  $t_x$  may only refer to previously defined functions (no recursion).

## Examples

- **Definition:** Let  $x$  and  $y$  be natural numbers. Then the *square sum* of  $x$  and  $y$  is the sum of the squares of  $x$  and  $y$ .

$$\text{squaresum} : \mathbb{N} \times \mathbb{N} \rightarrow \mathbb{N}$$

$$\text{squaresum}(x, y) := x^2 + y^2$$

- **Definition:** Let  $x$  and  $y$  be natural numbers. Then the *squared sum* of  $x$  and  $y$  is the square of  $z$  where  $z$  is the sum of  $x$  and  $y$ .

$$\text{sumsquared} : \mathbb{N} \times \mathbb{N} \rightarrow \mathbb{N}$$

$$\text{sumsquared}(x, y) := \mathbf{let} \ z = x + y \ \mathbf{in} \ z^2$$

- **Definition:** Let  $n$  be a natural number. Then the *square sum set* of  $n$  is the set of the square sums of all numbers  $x$  and  $y$  from 1 to  $n$ .

$$\text{squaresumset} : \mathbb{N} \rightarrow \mathcal{P}(\mathbb{N})$$

$$\text{squaresumset}(n) := \{\text{squaresum}(x, y) \mid x, y \in \mathbb{N} \wedge 1 \leq x \leq n \wedge 1 \leq y \leq n\}$$

## Predicate Definitions

A new predicate may be introduced by describing its truth value.

■ An **explicit predicate definition**

$$p \subseteq T_1 \times \dots \times T_n$$

$$p(x_1, \dots, x_n) :\Leftrightarrow F_x$$

- introduces a new  $n$ -ary **predicate symbol**  $p$  with
- a **type signature**  $T_1 \times \dots \times T_n$  with sets  $T_1, \dots, T_n$ ,
- a list of variables  $x_1, \dots, x_n$  (the **parameters**), and
- a formula  $F$  (the **body**) whose free variables occur in  $x_1, \dots, x_n$ ;
- case  $n = 0$ : the definition of a truth value constant  $p :\Leftrightarrow F_x$ .

■ We then know

$$\forall x_1 \in T_1, \dots, x_n \in T_n : p(x_1, \dots, x_n) \leftrightarrow F_x$$

The body  $F_x$  may only refer to previously defined predicates (no recursion).

## Examples

- **Definition:** Let  $x, y$  be natural numbers. Then  $x$  *divides*  $y$  (written as  $x|y$ ) if  $x \cdot z = y$  for some natural number  $z$ .

$$| \subseteq \mathbb{N} \times \mathbb{N}$$

$$x|y : \Leftrightarrow \exists z \in \mathbb{N} : x \cdot z = y$$

- **Definition:** Let  $x$  be a natural number. Then  $x$  *is prime* if  $x$  is at least two and the only divisors of  $x$  are one and  $x$  itself.

$$\text{isprime} \subseteq \mathbb{N}$$

$$\text{isprime}(x) : \Leftrightarrow x \geq 2 \wedge \forall y \in \mathbb{N} : y|x \rightarrow y = 1 \vee y = x$$

- **Definition:** Let  $p, n$  be natural numbers. Then  $p$  is a *prime factor* of  $n$ , if  $p$  is prime and divides  $n$ .

$$\text{isprimefactor} \subseteq \mathbb{N} \times \mathbb{N}$$

$$\text{isprimefactor}(p, n) : \Leftrightarrow \text{isprime}(p) \wedge p|n$$

## Implicit Function Definitions

A new function may be introduced by a condition on its result value.

### ■ An implicit function definition

$$f: T_1 \times \dots \times T_n \rightarrow T$$

$$f(x_1, \dots, x_n) := \mathbf{such} \ y: F_{x,y} \text{ (or: } \mathbf{the} \ y: F_{x,y})$$

- introduces a new  $n$ -ary function constant  $f$  with
- a type signature  $T_1 \times \dots \times T_n \rightarrow T$  with sets  $T_1, \dots, T_n, T$ ,
- a list of variables  $x_1, \dots, x_n$  (the parameters),
- a variable  $y$  (the result variable),
- a formula  $F_{x,y}$  (the result condition) whose free variables occur in  $x_1, \dots, x_n, y$ .

### ■ We then know

$$\forall x_1 \in T_1, \dots, x_n \in T_n : (\exists y \in T : F_{x,y}) \rightarrow (\exists y \in T : F_{x,y} \wedge y = f(x_1, \dots, x_n))$$

- If some value satisfies the condition, the function result is such a value.
- With **the** we claim that the value of  $f$  always exists and is unique.

The definition of a function by a formula (rather than a term).

## Examples

- **Definition:** A *root* of real number  $x$  is a real number  $y$  such that the square of  $y$  is  $x$ .

$$\text{aRoot}: \mathbb{R} \rightarrow \mathbb{R}$$

$$\text{aRoot}(x) := \mathbf{such} \ y: y^2 = x$$

- **Definition:** The *root* of non-negative real  $x$  is that real  $y$  such that the square of  $y$  is  $x$  and  $y \geq 0$ .

$$\text{theRoot}: \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}$$

$$\text{theRoot}(x) := \mathbf{the} \ y: y^2 = x \wedge y \geq 0$$

- **Definition:** Let  $m, n \in \mathbb{N}$  with  $n$  positive. Then the (*truncated*) *quotient*  $q \in \mathbb{N}$  of  $m$  and  $n$  is such that  $m = n \cdot q + r$  for some  $r \in \mathbb{N}$  with  $r < n$ .

$$\text{quotient}: \mathbb{N} \times \mathbb{N}_{>0} \rightarrow \mathbb{N}$$

$$\text{quotient}(m, n) := \mathbf{the} \ q: \exists r \in \mathbb{N}: m = n \cdot q + r \wedge r < n$$

- **Definition:** Let  $x, y$  be positive natural numbers. The *greatest common divisor* of  $x$  and  $y$  is the greatest such number that divides both  $x$  and  $y$ .

$$\text{gcd}: \mathbb{N}_{>0} \times \mathbb{N}_{>0} \rightarrow \mathbb{N}_{>0}$$

$$\text{gcd}(x, y) := \mathbf{the} \ z: z|x \wedge z|y \wedge \forall z' \in \mathbb{N}_{>0}: z'|x \wedge z'|y \rightarrow z' \leq z$$

# Predicates versus Functions

A predicate can give rise to functions in two ways.

- A **predicate**:

$$\text{isprimefactor} \subseteq \mathbb{N} \times \mathbb{N}$$

$$\text{isprimefactor}(p, n) :\Leftrightarrow \text{isprime}(p) \wedge p|n$$

- An **implicitly defined function**:

$$\text{someprimefactor} : \mathbb{N} \rightarrow \mathbb{N}$$

$$\text{someprimefactor}(n) := \mathbf{such} \ p : \text{isprime}(p) \wedge p|n$$

- An **explicitly defined function** whose result is a set:

$$\text{allprimefactors} : \mathbb{N} \rightarrow \mathcal{P}(\mathbb{N})$$

$$\text{allprimefactors}(n) := \{p \in \mathbb{N} \mid \text{isprime}(p) \wedge p|n\}$$

The preferred style of definition is a matter of taste and purpose.

## Specifying Problems

An important role of logic in computer science is to specify problems.

- The specification of a (computational) problem

**Input:**  $x_1 \in T_1, \dots, x_n \in T_n$     **where**  $I_x$

**Output:**  $y_1 \in U_1, \dots, y_m \in U_m$     **where**  $O_{x,y}$

- consists of a list of **input variables**  $x_1, \dots, x_n$  with types  $T_1, \dots, T_n$ ,
- a formula  $I_x$  (the **input condition** or **precondition**) whose free variables occur in

$$x_1, \dots, x_n$$

- a list of **output variables**  $y_1, \dots, y_m$  with types  $U_1, \dots, U_m$ , and
- a formula  $O_{x,y}$  (the **output condition** or **postcondition**) whose free variables occur in

$$x_1, \dots, x_n, y_1, \dots, y_m$$

The specification is expressed with the help of auxiliary functions and predicates.

## Example

**Problem:** extract from a finite sequence  $s$  of natural numbers a subsequence  $t$  of length  $n$  starting at position  $p$ .

Example:  $s = [2, 3, 5, 7, 5, 11], p = 2, n = 3 \rightsquigarrow t = [5, 7, 5]$

**Input:**  $s \in \mathbb{N}^*, n \in \mathbb{N}, p \in \mathbb{N}$  where

$$n + p \leq \text{length}(s)$$

*(subsequence is in range of array)*

**Output:**  $t \in \mathbb{N}^*$  where

$$\text{length}(t) = n \wedge$$

*(length of result sequence)*

$$\forall i \in \mathbb{N}_n: t(i) = s(i + p)$$

*(content of result sequence)*

# The Adequacy of Specifications

**Input:**  $x$  where  $I_x$  **Output:**  $y$  where  $O_{x,y}$

- Is precondition satisfiable? ( $\exists x: I_x$ )  
Otherwise no input is allowed.
- Is precondition not trivial? ( $\exists x: \neg I_x$ )  
Otherwise every input is allowed, why then the precondition?
- Is postcondition always satisfiable? ( $\forall x: I_x \rightarrow \exists y: O_{x,y}$ )  
Otherwise no implementation is legal.
- Is postcondition not always trivial? ( $\exists x, y: I_x \wedge \neg O_{x,y}$ )  
Otherwise every implementation is legal.
- Is result unique? ( $\forall x, y_1, y_2: (I_x \wedge O_{x,y}[y_1/y] \wedge O_{x,y}[y_2/y] \rightarrow y_1 = y_2)$ )  
Whether this is required, depends on our expectations.

Ask these questions to ensure that specification expresses your intentions.

## Example: The Problem of Integer Division

**Input:**  $m \in \mathbb{N}, n \in \mathbb{N}$    **Output:**  $q \in \mathbb{N}, r \in \mathbb{N}$  where  $m = n \cdot q + r$

- The postcondition is always satisfiable but not trivial.
  - For  $m = 13, n = 5$ , e.g.  $q = 2, r = 3$  is legal but  $q = 2, r = 4$  is not.
- But the result is not unique.
  - For  $m = 13, n = 5$ , both  $q = 2, r = 3$  and  $q = 1, r = 8$  are legal.

**Input:**  $m \in \mathbb{N}, n \in \mathbb{N}$    **Output:**  $q \in \mathbb{N}, r \in \mathbb{N}$  where  $m = n \cdot q + r \wedge r < n$

- Now the postcondition is not always satisfiable.
  - For  $m = 13, n = 0$ , no output is legal.

**Input:**  $m \in \mathbb{N}, n \in \mathbb{N}$  where  $n \neq 0$    **Output:**  $q \in \mathbb{N}, r \in \mathbb{N}$  where  $m = n \cdot q + r \wedge r < n$

- The precondition is not trivial but satisfiable.
  - $m = 13, n = 0$  is not legal but  $m = 13, n = 5$  is.
- The postcondition is always satisfiable and result is unique.
  - For  $m = 13, n = 5$ , only  $q = 2, r = 3$  is legal.

## Example: The Problem of Linear Search

**Problem:** given a finite integer sequence  $a$  and an integer  $x$ , determine the smallest position  $p$  at which  $x$  occurs in  $a$  ( $p = -1$ , if  $x$  does not occur in  $a$ ).

Example:  $a = [2, 3, 5, 7, 5, 11], x = 5 \rightsquigarrow p = 2$

**Input:**  $a \in \mathbb{Z}^*, x \in \mathbb{Z}$

**Output:**  $p \in \mathbb{N} \cup \{-1\}$  where

**let**  $n = \text{length}(a)$  **in**

**if**  $\exists p \in \mathbb{N}_n : a(p) = x$

*( $x$  occurs in  $a$ )*

**then**  $p \in \mathbb{N}_n \wedge a(p) = x \wedge$

*( $p$  is the index of some occurrence of  $x$ )*

$(\forall q \in \mathbb{N}_n : a(q) = x \rightarrow p \leq q)$

*( $p$  is the smallest such index)*

**else**  $p = -1$

All inputs are legal; the result always exists and is uniquely determined.

## Example: The Problem of Binary Search

**Problem:** given a finite integer sequence  $a$  that is sorted in ascending order and an integer  $x$ , determine some position  $p$  at which  $x$  occurs in  $a$  ( $p = -1$ , if  $x$  does not occur in  $a$ ).

Example:  $a = [2, 3, 5, 5, 5, 7, 11], x = 5 \rightsquigarrow p \in \{2, 3, 4\}$

**Input:**  $a \in \mathbb{Z}^*, x \in \mathbb{Z}$  where

let  $n = \text{length}(a)$  in

$\forall k \in \mathbb{N}_{n-1}: a(k) \leq a(k+1)$  *(a is sorted)*

**Output:**  $p \in \mathbb{N} \cup \{-1\}$  where

let  $n = \text{length}(a)$  in

if  $\exists p \in \mathbb{N}_n: a(p) = x$  *(x occurs in a)*

then  $p \in \mathbb{N}_n \wedge a(p) = x$  *(p is the index of some occurrence of x)*

else  $p = -1$

Not all inputs are legal; for every legal input, the result exists but is not unique.

## Example: The Problem of Sorting

**Problem:** given a finite integer sequence  $a$ , determine that permutation  $b$  of  $a$  that is sorted in ascending order.

Example:  $a = [5, 3, 7, 2, 3] \rightsquigarrow b = [2, 3, 3, 5, 7]$

**Input:**  $a \in \mathbb{Z}^*$

**Output:**  $b \in \mathbb{Z}^*$  where

let  $n = \text{length}(a)$  in

$\text{length}(b) = n \wedge$

$(\forall k \in \mathbb{N}_{n-1}: b(k) \leq b(k+1)) \wedge$

*(b is sorted)*

$\exists p \in \mathbb{N}_n^* :$

*(b is a permutation of a)*

$(\forall k_1 \in \mathbb{N}_n, k_2 \in \mathbb{N}_n: k_1 \neq k_2 \rightarrow p(k_1) \neq p(k_2)) \wedge$

$(\forall k \in \mathbb{N}_n: a(k) = b(p(k)))$

All inputs are legal; the result always exists and is uniquely determined.

# Implementing Problem Specifications

**Input:**  $x_1 \in T_1, \dots, x_n \in T_n$  **where**  $I_x$

**Output:**  $y_1 \in U_1, \dots, y_m \in U_m$  **where**  $O_{x,y}$

- Specification demands definition of function  $f: T_1 \times \dots \times T_n \rightarrow U_1 \times \dots \times U_m$  with property

$\forall x_1 \in T_1, \dots, x_n \in T_n : I_x \rightarrow \mathbf{let} (y_1, \dots, y_m) = f(x_1, \dots, x_n) \mathbf{in} O_{x,y}$

- For all arguments  $x_1, \dots, x_n$  that satisfy the input condition,
- the result  $(y_1, \dots, y_m)$  of  $f$  satisfies the output condition.

- The specification itself already implicitly defines such a function:

$f(x_1, \dots, x_n) := \mathbf{such} y_1, \dots, y_m : I_x \rightarrow O_{x,y}$

- However, actually we want an explicitly defined function (computer program):

$f(x_1, \dots, x_n) := t_x$

A core goal of computer science is to specify problems, to implement the specifications, and to verify the correctness of the implementation (e.g., by formal methods).
